研究背景	The WNT gene family consists of structurally related genes which encode secreted signaling proteins. The se proteins have been implicated in oncogenesis and in several developmental processes, including regul ation of cell fate and patterning during embryogenesis. This gene encodes a member of the WNT family t hat signals through both the canonical and non-canonical WNT pathways. This protein is a ligand for the s even transmembrane receptor frizzled-5 and the tyrosine kinase orphan receptor 2. This protein plays an essential role in regulating developmental pathways during embryogenesis. This protein may also play a role in oncogenesis. Mutations in this gene are the cause of autosomal dominant Robinow syndrome. Alte rnate splicing results in multiple transcript variants.
