靶点信息

研究背景	As a monomeric immunoglobulin that is predominately involved in the secondary antibody response and the only isotype that can pass through the human placenta, Immunoglobulin G (IgG) is synthesized and s ecreted by plasma B cells, and constitutes 75% of serum immunoglobulins in humans. IgG antibodies prot ect the body against the pathogens by agglutination and immobilization, complement activation, toxin ne utralization, as well as the antibody-dependent cell-mediated cytotoxicity (ADCC). IgG tetramer contains t wo heavy chains (50 kDa) and two light chains (25 kDa) linked by disulfide bonds, that is the two identic al halves form the Y-like shape. IgG is digested by pepsin proteolysis into Fab fragment (antigen-binding f ragment) and Fc fragment ("crystallizable" fragment). IgG1 is most abundant in serum among the four Ig G subclasses (IgG1, 2, 3 and 4) and binds to Fc receptors (FcγR) on phagocytic cells with high affinity.
