靶点信息

| 研究背景 | The protein encoded by this gene is a member of the fibroblast growth factor receptor (FGFR) family, whe re amino acid sequence is highly conserved between members and throughout evolution. FGFR family m embers differ from one another in their ligand affinities and tissue distribution. A full-length representativ e protein consists of an extracellular region, composed of three immunoglobulin-like domains, a single hy drophobic membrane-spanning segment and a cytoplasmic tyrosine kinase domain. The extracellular por tion of the protein interacts with fibroblast growth factors, setting in motion a cascade of downstream sig nals, ultimately influencing mitogenesis and differentiation. This particular family member binds both acid ic and basic fibroblast growth factors and is involved in limb induction. Mutations in this gene have been associated with Pfeiffer syndrome, Jackson-Weiss syndrome, Antley-Bixler syndrome, osteoglophonic dysp lasia, and autosomal dominant Kallmann syndrome 2. Chromosomal aberrations involving this gene are a ssociated with stem cell myeloproliferative disorder and stem cell leukemia lymphoma syndrome. Alterna tively spliced variants which encode different protein isoforms have been described; however, not all vari ants have been fully characterized. |
